

CARBON BASED MATERIALS FOR CADMIUM AND ZINC REMEDIATION OF CONTAMINATED WATER

Yihan Zhao¹ and M Anne Naeth¹

BACKGROUND

The Problem

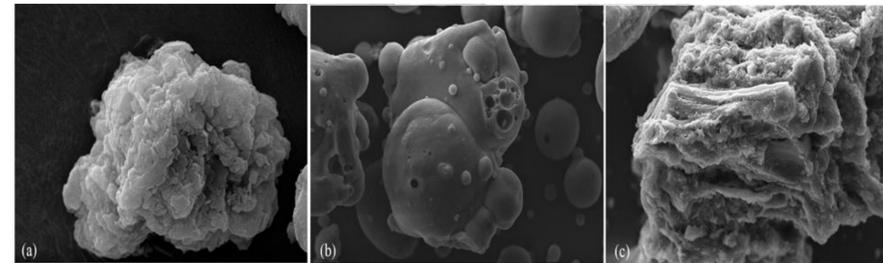

- Heavy metals are toxic at low concentrations
- Contamination in water is a priority concern for the environment and public health
- Conventional methods are expensive, time consuming and low efficiency

Research Objectives

- Investigate adsorption effectiveness of Cd(II) and Zn(II) removal from contaminated water
- Understand adsorption mechanisms for metal remediation

New Technology

- Low cost porous carbon based materials
- Sourced from agricultural and industrial waste

Nano humus Humic powder Biochar
(lignite wastes) (cattle manure)

CONCLUSIONS

Summary

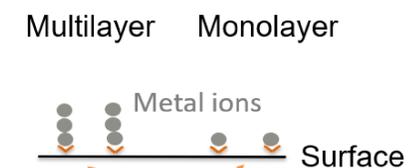

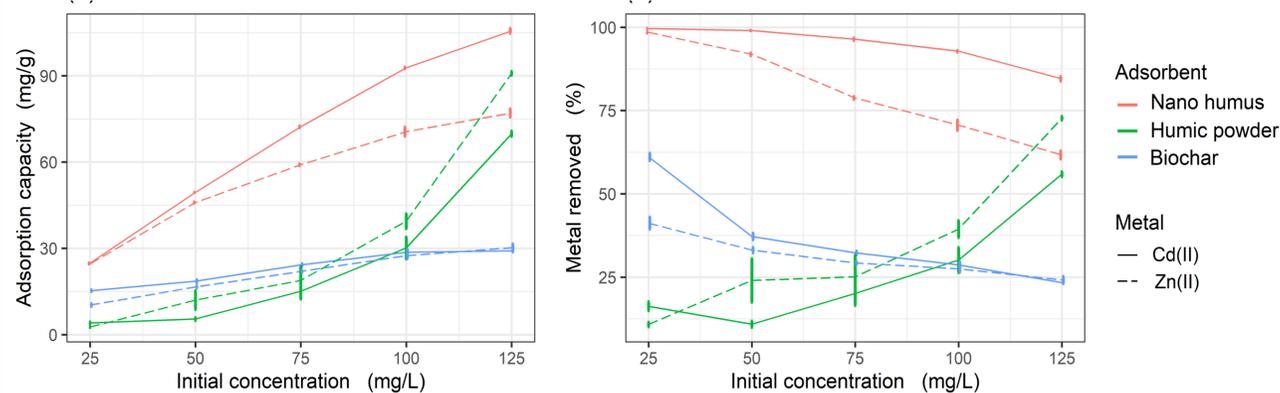

- Nano humus was most effective adsorbent, followed by biochar and humic powder
- Both nano humus and biochar were recommended for metal remediation from contaminated water

Research Benefits

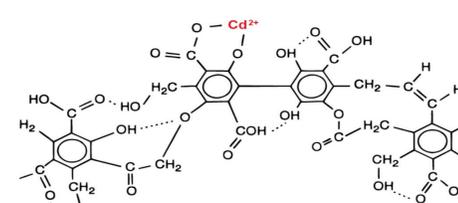

- Low cost, efficient, rapid adsorbents
- Reduce remediation costs
- Reduce remediation time
- New remediation alternatives
- Global implications, widely applicable throughout the world

RESULTS

- Materials could bond multiple layers of metal molecules on their surface
- Metal ion initial concentration greatly influenced adsorption
- Nano humus and biochar had higher affinity for Cd(II) than Zn(II)
- Humic powder had higher affinity for Zn(II) than Cd(II)

Adsorption mechanism

Structure of nano humus
